SUMMARY

Rationale: Recent GSK experimental data from approximately 1,000 children suggested that those receiving Paroxetine were more likely to report adverse events suggestive of suicidal thinking and behaviour, as compared to patients receiving placebo. No patients committed suicide in these studies. The adverse event data is different to information from adult trials which have found no increased risk in the reporting of adverse events suggestive of suicidal thinking and behaviour.

Objective: To investigate whether the risk of reported suicidal thinking and behaviour was similar between adults and children during use of SSRI and non-SSRI antidepressants and during use of Paroxetine and other SSRI antidepressants.

Methods: i) A retrospective observational cohort study, using 158,530 patients identified from the new “full feature” General Practice Research Database to estimate and compare risk of suicidal behaviour by antidepressant use and patient age. ii) A nested case control study using cases and controls drawn from the cohort to investigate risk of suicidal behaviour associated with antidepressant use stratified by age and duration of use after controlling for patient history.

Results: In our cohort analysis, we found that relative to non-SSRI users, SSRI users had a greater history of medical events that were likely to increase their risk of suicidal behaviour prior to initiation of therapy. SSRI users were more likely to have had a record of prior suicidal behaviour, psychiatric referral, psychosis, acute cardiovascular disease or stroke and less likely to have had a record of a major traumatic life event or prior diagnoses of insomnia or epilepsy. Compared to users of all other SSRIs combined, users of paroxetine were significantly more likely to have had a history of prior psychiatry referral and insomnia, and less likely to have had a prior major traumatic life event, prior psychoses or multiple sclerosis. Paroxetine patients aged 18 and under had an even greater history of these factors which may increase the risk of suicidal behaviour.

After adjusting for these patient history factors up to the time of initiation of therapy, in the cohort analysis we found no statistically significant differences between SSRI and non-SSRI users (Hazard Ratio=0.96, 95%CI=0.85-1.08) or between users of Paroxetine and other SSRIs (individually and in aggregate) for patients aged over 18. For patients aged 18 and under, we found a statistically significant increase in risk for SSRI users relative to non SSRI users (HR=1.90, 95%CI=1.29-2.8), and for users of Paroxetine relative to all other SSRI's combined (HR=1.58, 95%CI=1.17-2.14).

We also performed analyses using the cohort data, to investigate whether the relationship between risk of suicidal behaviour associated with SSRI or Paroxetine use differed by the phase of therapy (initiation, maintenance, discontinuation). In these analyses, we found that during the maintenance period people 18 years and under were at a significantly increased risk of suicidal behaviour associated with SSRI use relative to non-SSRI use (HR=2.08, 95%CI=1.07-4.04) and with Paroxetine use relative to all other SSRI's

combined (HR=2.15, 95%CI=1.36-3.40). The limitation of this analysis was that the maintenance period was highly variable between patients; 99% of patients ranged between 1 and 1037 days of maintenance therapy. As a result we felt the categorisation of the maintenance period was too broad to allow for an accurate investigation of the influence of duration of therapy on the risk of suicidal behaviour associated with use of different medications. Adjustment for time since entry into the cohort was addressed more appropriately within the case-control study.

In the nested-case control analyses, after adjusting for patient history, among patients over 18 years old we found a significant decrease in suicidal behaviour associated with SSRI use (adj OR=0.84, 95%CI=0.71-0.99) and a small, but not statistically increased risk associated with Paroxetine use relative to all other SSRI use (adj OR=1.08, 95%CI=0.87-1.34). We found no significant interaction between suicidal behaviour, duration and treatment associated with SSRI use relative to non-SSRI use or Paroxetine use relative to use of all other SSRI's.

Among patient aged 18 years and younger, we found a significantly elevated risk associated with SSRI use relative to non-SSRI use (OR=1.82, 95%CI=1.04-3.21). We found an elevated, but not statistically increased risk associated with Paroxetine use relative to use of all other SSRI's (OR=1.39, 95%CI=0.89-2.16).

Among patients aged 18 and younger, we found no significant interaction between suicidal behaviour risk, duration of therapy and SSRI use relative to non-SSRI use. We found increased risk with different durations of exposure but no trend associated with increasing duration of medication use: 1-30 days (OR=1.55, 95%CI=0.79-3.02) of 31-60 days (OR=3.24, 95%CI=1.11-9.44), 61-90 days (OR=1.52, 95%CI=0.25-9.42), 91+ days (OR=3.27, 95%CI=0.69-15.55). None of these estimates, with the exception of the estimate for 31-60 days of exposure, were significantly greater than one or statistically different from each other. Given that this estimate occurred in the 31-60 day period and the estimate for the next period 61-90 days is considerable smaller (OR=1.52) it may be due to a combination of small sample and an artefact of data reporting.

For patients aged 18 and younger, we found similar results for Paroxetine use relative to use of all other SSRI's. We found some evidence of a trend associated with increasing duration of therapy : 1-30 days (OR=1.11, 95%CI=0.59-2.09), 31-60 days (OR=1.51, 95%CI=0.55-4.13), and 61-90 days (OR=1.64, 95%CI=0.35-7.69), and 91+ days (OR=2.27, 95%CI=0.66-7.80). However, none of the estimates were statistically different from one or statistically different from each other; but this may have been attributable to lack of precision due to small sample size.

Conclusion: Our study found no pattern of increased risk of suicidal behaviour associated with SSRI use relative to non-SSRI use or paroxetine use relative to use of other SSRI's among adults. The increased risk of suicidal behaviour associated with use of SSRI and Paroxetine antidepressants was confined to adolescents (10-18 years). We also found that this increased risk may differ by duration of SSRI use and Paroxetine use but there was no trend associated with increasing duration of use. We also found that prior to initiation of therapy, SSRI users and Paroxetine users had a greater medical history of psychiatric referrals and suicidal behaviour relative to other drug users.

Although we adjusted for these differences in our analyses, because the majority of the events measured in the study were suicidal attempts, it was likely that we under-represented the influence of prior suicidal thinking among users of SSRI's or Paroxetine on the study results.

As a result, we conclude that children using SSRI medications may be at an increased risk of suicidal behaviour, and Paroxetine users may be at a slightly elevated risk relative to users of other SSRI medications, However, because these increases are relatively small, they may be attributable to the unmeasured confounding by indication due to prescribing of SSRI's and Paroxetine to patients with an elevated background risk of suicidal behaviour.

Key findings

Background

- Children (10-18 years) taking SSRI's and Paroxetine were more likely to have evidence of suicidal history and psychiatric referral prior to initiation of therapy.

Cohort Analyses

- No increased risk with SSRI relative to non-SSRI use or Paroxetine relative to other SSRI for adults.
- Small, statistically significant, increase in risk among children for SSRI use relative to non-SSRI and Paroxetine relative to other SSRI.

Case-control Analyses

- No increased risk with SSRI relative to non-SSRI or Paroxetine relative to other SSRI for adults.
- Small, but not statistically significant, increase in risk among children with SSRI relative to non-SSRI and Paroxetine relative to other SSRI.
- Increased risk with duration but no significant trend between drug use, suicidal behaviour and duration of therapy.

Conclusion

- Children using SSRI medications may be at an increased risk of suicidal behaviour, and Paroxetine users may be at a slightly elevated risk relative to users of other SSRI medications,
- Differences are relatively small, and may be attributable to unmeasured confounding by indication due to prescribing of SSRI's and Paroxetine to patients with an elevated background risk of suicidal behaviour.

INTRODUCTION

A link between use of SSRI medications and suicidal behaviour has been a concern since the introduction of Fluoxetine in the 1980's (17,16). A meta-analysis of controlled clinical data conducted in 1991 (18) did not show evidence of an association between treatment-emergent suicidal ideation and use of fluoxetine. Since 1991 there have been additional case reports (36) and extensive media coverage about a link between suicide and Fluoxetine use. This has broadened to a concern with other SSRI medications as they have been introduced (37). This concern has prompted extensive review of public and company held information over the past 15 years to determine the presence of an increased risk of suicide and suicidal behaviour associated with SSRI use. Most recently, the FDA compared the rates of completed suicide for 48,277 adult depressed patients using SSRI's , other antidepressants and placebos within clinical trials. Their conclusions were that use of "existing subclasses of drugs has little effect on suicide rates in clinical trials." (19).

Paroxetine is an antidepressant that belongs to the class of selective serotonin reuptake inhibitors (SSRIs). It was launched in the United States in 1993 under the trade name Paxil, and in Europe in 1991 as Seroxat/Deroxat (3). In addition to its original indication as treatment for major depression, the drug has gained FDA and worldwide approval for indications in generalized anxiety disorder (GAD), social anxiety disorder (SAD), post-traumatic stress disorder (PTSD), obsessive-compulsive disorder (OCD), and panic disorder (PD) (3). Paroxetine has proven to be an effective treatment for mood and anxiety disorders in over 6,700 studied patients worldwide (4). Clinical trials of Paroxetine have shown that the drug is well tolerated and has a favourable benefit-risk profile (5).

Recent GSK experimental data of 1,000 children suggested that those receiving Paroxetine were more likely to have suicidal thoughts, as compared to similarly depressed children on placebo. This is contrary to information from adult trials which have found no increased risk of suicide, suicidal behaviour or suicidal thoughts. No studies have been conducted to evaluate the similarity between use of antidepressants and suicidal behaviour risk in adults and children.

To address this limitation in current research, we used the UK General Practice Research Database to investigate the similarity between adults and children in the relationship between the use of antidepressant medications and the risk of suicidal behaviour.

OBJECTIVES

The primary goal of this study is to investigate the association between specific antidepressant use and suicidal behaviour, and to assess whether any associations found can be explained by differences in the prior risk of suicidal behaviour between treatment cohorts.

Consequently, this study will address three primary research objectives:

- The prescribing patterns of non-SSRIs, SSRIs and Paroxetine as they relate to baseline risks for suicidal behaviour.
- The possible association between antidepressant use and suicide related events after initiation of therapy.
- The possible difference in the association between antidepressant use and suicidal behaviour in those aged 18 and under relative to those aged over 18 years.

METHODS

Study Design

Using patients identified from the new “Full Feature” UK General Practice Research Database between 1988 and 2003, we compared the medical history and rates of suicidal events among a retrospective cohort of new users of SSRI and non-SSRI antidepressants. We also conducted a nested case-control study to investigate for the presence of higher risk in different patient age, gender, duration and treatment discontinuation sub-groups after controlling for the influence of patient history factors that could bias the comparison of suicide risk between users of individual drugs.

Base population

Patients were drawn from the UK "Full Feature" General Practice Research database (GPRD). The GPRD contains detailed information on diagnoses, prescribing, investigations, risk factors, outcomes and hospital referrals, together with basic demographic information for a sample of patients from representative general practices throughout the UK. Patient data included in the GPRD was drawn from the computer systems used by general practitioners (GPs) to maintain the clinical records within their practices, and contain all records deemed relevant to patient care. Data quality has been monitored continuously by the UK Medicines and Healthcare Regulatory Agency (MHRA). Practices that fail to maintain the required standards are removed. This study was approved by the scientific and ethical advisory group for the GPRD.

3.3 Study Population

Patients were considered eligible for inclusion in the study if they met the following conditions;

- If they were deemed to be "Acceptable" patients, as defined by the data providers. The status of "Acceptable" is based on consistency within and between patient registration and demographic details.
- If they had at least 18 months of "up to standard" (UTS) registration on the GPRD prior to the first date of antidepressant prescribing. The date when a general practices' data is deemed to be "Up to standard" is defined by the database providers, based on a

suite of internal checks of the completeness and continuity of recording. The date of first antidepressant prescribing is taken as the first ever record of an antidepressant prescription on the GPRD. Patients with an antidepressant prescription within the first 18 months of UTS registration, or in the period prior to the UTS date, are excluded.

- If they had a diagnosis of either major depression, or an anxiety disorder (OCD, SAD, GAD, PTSD, or PD) in the 18 months prior to their initial antidepressant prescription. This need not be the first record of depression or anxiety.
- If they were aged 10 years or older on the date of the first antidepressant prescription
- If they were prescribed only a single antidepressant on the date of first prescribing.

Antidepressant exposure

Patients prescribed an antidepressant were identified by searching all records in the GPRD where the record type was given as "Therapy". Antidepressants of interest were those that are currently marketed in the U.K., according to the British National Formulary (BNF, Section 4.3) from March, 2003. This included tricyclic and related medications, monoamine-oxidase inhibitors, selective serotonin re-uptake inhibitors and other antidepressant drugs. Flupenthixol was not considered because its use in the UK is primarily as an antipsychotic medication. Antidepressants that had become unavailable before March, 2003 (nefazodone, protriptyline and viloxazine), and products containing multiple drug substances were not included as study drugs, although these were considered when determining the date of first antidepressant use and any changes in treatment. Patients with prior use of flupenthixol or a discontinued or multi-constituent antidepressant medication were excluded from the study. A full list of the antidepressant products considered is given in [Appendix 4](#).

The earliest antidepressant prescription for each patient was defined as the patient's index date. Exposure was taken as beginning at the index date and continuing until 30 days after the end of the patient's last prescription within the first period of continuous treatment, or the date when a new antidepressant was either added to, or replaced, the initial drug, which ever came first. In analyses using aggregated treatment groups, a patient was considered to have changed treatment, even if they switched from one product to another within the same therapy group.

Individual prescription records were concatenated to create continuous periods of exposure. Prescriptions were deemed to be "continuous" if the gap between the end of the preceding prescription and the start of the next was less than or equal to 30 days. Overlapping prescriptions were truncated, and an ongoing prescription was deemed to end on the date a subsequent prescription was issued. A prescription starting more than 30 days after the end of the previous treatment was taken as a new period of exposure, rather than as a continuation of the previous treatment.

The duration of each prescription record was taken as the duration recorded by the GP, or computed directly as the total prescription quantity divided by the daily dose, where each was recorded. Otherwise, duration was imputed based on product-specific median values.

Where the total prescription quantity information was available but the daily dose was missing, duration was calculated from the recorded quantity and the product-specific median daily dose. Likewise, where the daily dose information was available but the total prescription quantity was missing, duration was calculated from the recorded dosage and the product-specific median prescribing quantity.

The product-specific median duration was assigned to any prescription where both the dosage and quantity information were missing, or where the recorded duration was inconsistent with the recorded daily dose and prescription quantity information. It was assumed that the recorded quantity referred to the number of packs prescribed, rather than the number of tablets, for prescriptions where the duration was calculated to be less than seven days, and duration was recalculated accordingly. However, all remaining durations were deemed acceptable, and no conditions were applied for the maximum length of an individual prescription.

Suicidal Behaviour Definition and Measures

Events of interest were identified based on the presence of a coded record of suicidal behaviour where the record type was given as either "Clinical" or "Referral". A list of the Medcodes used to define suicidal behaviour is given in [Appendix 3](#). Additionally, the free text of death records were searched for keywords relating to suicide, and any additional records identified in this way were also included as potential suicidal events. The list of keywords used for this text search is listed in the same section of the Appendices.

A substantial number of all the suicidal events identified on, or after the index date, occurred on the day of first prescribing. Additionally, a greater proportion of SSRI users appeared to have a record of suicidal behaviour on the date of prescribing compared to users of non-SSRIs (see [Appendix 5](#)). Taken together, this information indicated that suicidal behaviour was often the reason for the initiation of antidepressant therapy and that this was more commonly the case among SSRI users relative to non-SSRI users.

As a result, for the purposes of this study, an incident suicidal behaviour was defined as the first behaviour occurring after the index date and within the first period of continuous exposure. These instances were considered "events" in the following cohort and case-control analyses. The underlying assumption in these analyses is that records of suicidal behaviour on the day of first prescribing represent the indication for treatment. These behaviours were then included in the description of prior suicidal events. No distinction was made between completed suicide, attempted suicide, suicidal ideation, and intentional self-harm. All results using this definition are presented in [Appendix 1](#). Unless stated otherwise, all references to results tables refer to this appendix.

All analyses presented within the Results section use this definition of event status. To describe the impact of assuming that all events occurring on the same day as start of therapy were not related to therapy, we have also presented analyses that define suicidal behaviour on the index date of therapy as an "event." These results are presented in the [Appendix 2](#) and are discussed within the Results section in comparison with the primary results.

Case assignment and clinical review

Incident suicidal events during the first period of antidepressant exposure were identified from consideration of the coded and free text information contained within the database. The complete database history of each patient included in the cohort was searched for information indicating the presence of possible suicidal behaviour. The non-coded or free-text comments associated with each of these records were requested from the GPRD database provider. Because this free-text information may contain personal information, it was not directly accessible to the investigators at GSK. All personal information was removed by the GPRD database provider prior to providing the free-text information to GSK.

Each patient with evidence of possible suicidal behaviour was assigned a case status based on an algorithm that was weighted toward assignment of a positive case status in the absence of contradictory information. Not all potential events had associated free-text. Events without such free-text were assumed to be cases of suicidal behaviour.

Records with free-text explicitly confirming the event were considered as true suicidal behaviour. Records with free-text explicitly indicating the absence of suicidal behaviour, were not considered to represent a true suicidal behaviour. All other records with free text were sent for review to two different clinicians. Where there was uncertainty about the status of an event, agreement was reached by consensus between the researchers and two clinicians.

Initially, only the first suicidal behaviour for each patient was considered as a possible event. Where the first entry was subsequently considered not to represent a true suicidal behaviour, the records of these patients were searched for further suicidal records during the remainder of their therapy duration and for up to 30 days after discontinuation of their therapy. Any additional records found in this way were then subject to the same process of review as above.

Patient medical history

All patient records on or before the index prescription date were examined for medical history potentially related to an increased risk of suicidal behaviour. This included the following medical diagnoses: major depression, anxiety, substance abuse (including alcohol), prior suicidal behaviour, insomnia (based on computerised medical records alone), psychoses, malignant cancer (all sites), acute cardiovascular events (MI or unstable angina), stroke, epilepsy, multiple sclerosis, and Huntington's disease.

A record of a psychiatric referral or hospitalisation was considered as a proxy for psychiatric severity. We also characterised patients by age at first treatment, gender, length of medical history prior to index date and presence of major life events as recorded by the GP. The list of medical codes defining each condition are given the [Appendix 4](#).

For the case-control analysis, age was recalculated as age at event date (or matched date for controls) and patients were further classified based on current exposure to concomitant medications that may increase the risk of suicidal behaviour or produce

depression or mania (35). This included oral steroids, isotretinoin, alpha/beta interferon, cholesterol-lowering drugs, digoxin and calcium channel blockers. The duration of concomitant medication use was calculated using similar methods as those applied to antidepressant records. Patients were considered exposed to a concomitant medication throughout the duration of the prescription and for the 30 days following discontinuation of therapy. The therapy codes describing the medications considered in this study are detailed in the [Appendix 4](#).

Database Validation sub-study

The validity of the GPRD has been demonstrated in several previous studies. The information on all patient referrals and hospitalisations contained in the manual records for the GP have been found to appear in the computerised database over 90% of the time (22-24). Most recently, Jick and colleagues (2003) have further demonstrated the quality and completeness of the computerised data (25). In addition, data quality is monitored continuously by the GPRD database provider. GP practices that fail to maintain the required standards are removed and their data excluded from the database.

We conducted a validation sub-study to estimate the sensitivity and specificity of our database-based definition of a suicidal event. We selected from our cohort of SSRI and non-SSRI users a sample of 2043 patients with at least one record of suicidal behaviour on the GPRD and 217 "control" patients with no record of suicidal behaviour. Patient identity numbers, and the date of first antidepressant prescribing on the GPRD, were provided to the GPRD database provider to use in identifying the appropriate General Practice office to contact for each patient.

The GPRD database provider sent questionnaires to the practice asking for details of any suicidal behaviour before, and on or after, the data of first antidepressant therapy. Details of suicidal thoughts, suicide attempts, completed suicides, and non-suicidal self harm were requested for each patient. GPs were not made aware of whether the patients had been selected by the researchers as a "case" (with a record of suicidal behaviour) or a "control". Only anonymised information was provided to the investigators at GSK. We estimated the accuracy of our disease classification data by estimating sensitivity, specificity, agreement (Simple agreement and Kappa) and positive predictive value of the database definition relative to the GP information.

ANALYSES

Cohort analyses

Demographic and prior medical history information up to the time of cohort entry was compared across treatment cohorts as a marker of pre-existing risk of suicidal behaviour. Comparison of demographic characteristics were made with Chi-square tests. Comparison of patient history information was performed with odds ratios and 95% confidence intervals estimated using unadjusted and adjusted logistic regression.

Adjusted analyses controlled for age (See [Table 1](#) for group definition), gender and length of patient history prior to cohort entry.

We compared the incidence of suicidal behaviours between SSRI and Non-SSRI users, paroxetine relative to other SSRIs combined (excluding paroxetine) and paroxetine relative to individual SSRI's (fluoxetine, sertraline, fluvoxamine and citalopram/escitalopram). All analyses considered incident (first time) users of an antidepressants and only the first period of exposure was included in the analyses. Incidence rates were calculated for the full population and for the age and gender subgroups, based on time at risk.

Time at risk was defined as starting one day after the date of first prescription (the index date + 1), and ending on the earlier date from the end of exposure or the date of the first suicidal behaviour following the index date. The underlying assumption in these analyses is that records of suicidal behaviour on the same day as the prescription represent the indication for treatment. As such, the index-date itself is not considered as time at risk. Suicidal behaviours on the index date are then included in the description of prior suicidal events. All comparisons were performed using Hazard ratio estimates (HR) and 95% confidence intervals. Cox proportional hazards models were used to adjust for the influence of baseline patient history factors as potential confounding variables in the comparison of event rates. Sub group analyses were performed by age group (≤ 18 , > 18 years). Further subgroup analyses of prior history of anxiety and/or depression were performed for patients aged 18 and under.

We also performed analyses where time at risk was further divided into the periods of "Initiation", "Maintenance" and "Discontinuation". "Initiation" refers to the first 30 days of exposure, "maintenance" to the period from day 31 until the end of the last prescription during the first period of continuous exposure, and "discontinuation" to the 30 day period following the end of the last prescription within the first period of continuous exposure. All analyses considering maintenance and discontinuation are conditional on patients remaining exposed (and free of a suicidal event) for sufficient time to enter these risk periods. The results of these analyses were potentially confounded by the large differences in the duration of the maintenance period between different patients. This was not addressed in this method of analyzing the cohort data, so adjustment for time since entry into the cohort was considered as part of design of the nested case-control study.

To examine a treatment effect trend across age groups, hazard ratios were calculated treating age as an unordered, categorical variable. Likelihood ratio tests were performed to investigate whether age could be considered ordinal, and if so, treatment by age interactions in linear, quadratic and cubic form were tested.

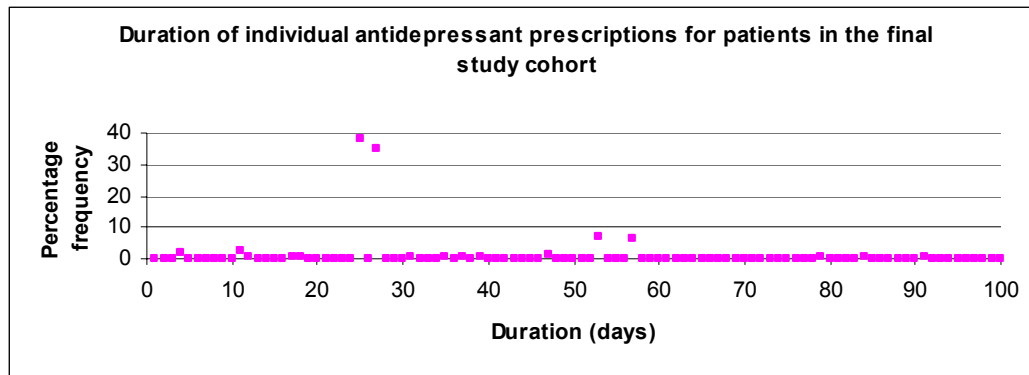

Case control analyses

Controls were matched to cases by age group (10-18, 19-29, 30-39, 40-49, 50-59, 60-69, 70-79, 80-89 and 90+ years), gender, GP practice and duration of history within the database prior to entry into the cohort, at the ratio of up to four controls to each case. Controls were selected from the pool of all patients at risk at the time of case's event

(with time expressed as days since entry into the cohort, rather than calendar date). As a result, a control could eventually become a case and a single control could be matched to more than one case. This method was selected to minimise the possibility that the controls were not representative of the base population (32). The only restriction applied was that patients subsequently becoming cases were not eligible to be selected as controls in the seven days prior to their suicidal event. This condition also required patients to have at least seven days of follow-up after being selected as controls to ensure that all controls were truly 'at risk' at the time of the case, and any delays in recording a suicidal event on the GPRD would not bias the matched sample.

Analyses to compare the risk of suicidal behaviour associated with SSRIs and non-SSRI antidepressant use included cases and controls drawn from all incident antidepressant users. A sub-set of the cases and a separate set of controls, drawn only from patients prescribed an SSRI, were used in analyses comparing Paroxetine with other SSRIs. This second set of controls was selected when considering only SSRIs to ensure that all patients contributed exposure information within this analysis.

In the case control analyses, all patient history variables were updated to reflect the patient's status on the date of the suicidal behaviour event (or a matched date for controls), rather than on the date of first prescribing. Duration of treatment exposure was categorised into five mutually exclusive categories corresponding to multiples of the most frequent prescription durations of 28/30 days (1-30 days, 31-60 days, 61-90 days, 91+ days) (see figure below) and discontinuation of therapy.

Demographic characteristics and patient history were summarised for cases and controls in both the SSRI/Non-SSRI dataset and the SSRI alone dataset.

The presence of potential statistical interactions within the data were evaluated to determine if the relationship between suicidal behaviour and use of antidepressant medications differed between different sub-groups of age, gender and duration of use. Within the multivariate conditional logistic regression models described above, we evaluated for the presence of treatment interactions with age, gender and duration of use. If significant interactions were found we evaluated for the presence of two and three way

interactions between these variables. Regardless of the presence of a statistically significant interaction within a given comparison, we also calculated the resulting strata specific Odds Ratios and 95% Confidence intervals to determine the presence of any descriptive information suggestive of effect modification by age, gender, and duration, and the three-way interactions of treatment, age and duration of therapy.

All comparisons between the treatment groups and strata specific associations were estimated using Odds Ratios (OR) and 95% confidence intervals derived from conditional logistic regression analyses controlling for patient history. Analyses entered all medical and concomitant exposure variables into forward stepwise regression models, with the entry criteria of $p \leq 0.1$. The entry criteria of $p \leq 0.1$ was chosen to ensure that all potentially important confounds were likely to be retained in the analyses. Details of the final variables retained within each model are given in [Appendix 6](#). Unadjusted analyses were also performed where only treatment effects and treatment interactions were retained in the model.

Sample Size and Study Power

Patient characteristics at first prescribing

The table below shows the levels of study power for detecting a difference in the prevalence of patient characteristics (from their medical history) between the exposed and unexposed groups. We have set the two-sided probability of a Type I error (alpha) at 0.05, and a range of prevalence estimates from 5% to 20% is used. These calculations are based upon a sample size of 6,000 patients in each cohort. According to our calculations, we will have 90% power or greater to detect an odds ratios as small as 1.2 , assuming prevalence of the given factor of 15%.

Study power (%) in detecting differences in patient medical history factors, according to prevalence of the factor and a range of odds ratios.

	Odds ratios				
Prevalence	1.2	1.3	1.4	1.5	1.6
0.05	61	91	98	99	99
0.10	87	99	99	100	100
0.15	95	99	100	100	100
0.20	98	99	100	100	100

Cohort Study of Suicidal Behaviour

The table below shows post-hoc power calculations for the crude hazard ratio comparison made within this study. The Type I error (alpha) is set to 0.05 and the sample sizes and number of events are those observed in the study.

For the overall SSRI vs. Non-SSRI comparison we have more than 90% power to detect that a hazard ratio of 1.2 is different to 1. For the Paroxetine comparisons, we have 90% power to detect that a hazard ratio in the region of 1.3-1.4 is different to 1. Similar power estimates are seen for the subgroups of patients aged over 18.

In the subgroup of patients aged 18 and under we have more than 90% power to detect that a hazard ratio of 1.5 is different to 1 for the overall SSRI vs. Non-SSRI comparison. Whereas, for the Paroxetine comparisons, we have 90% power to detect that a hazard ratio in the region of 1.9 is different to 1 (40).

Study power (%) in detecting differences in the cohort analyses (hazard ratios), according to the observed sample sizes and events.

Comparison	Alpha Level	N1	N2	Number Of Events	Hazard Ratio	Estimated Power
SSRIs vs. Non-SSRIs (All)	0.05	93305	65225	1359	1.1	0.478
					1.2	0.954

Case control Study of Suicidal Behaviour

We conducted a post-hoc analysis of the ability of our case-control sample to detect a statistically significant difference with respect to the main effect and several different potential interactions of age, treatment and duration. Hsieh FY and Lavori PW (2000), provide a simple formula for the number of cases required for a specified power, level of significance and hazard ratio to be detected, while adjusting for other factors using a Cox proportional hazard model. The correlation between the exposure and the remaining factors was calculated using linear regression on the observed data and substituted in this formula. The table below describes the minimum number of cases (controls of equal or greater number) to demonstrate treatment effects, treatment by age interactions and treatment by duration interactions. Based on these calculations, we estimate that we were able to evaluate with 80% power and 5% significance, an elevated risk of OR=1.1 with 237 or more cases and elevated risk of OR=1.5 or more with 56 more cases and elevated risk of OR=3 or more with 21 or more cases. We required slightly more cases to evaluate the difference in treatment effects across different strata of durations and considerable larger numbers to evaluate the interaction and age due to the small proportion of patients in our sample aged 10-18 years old.

OR	Treatment	Treatment by Age	Treatment by Duration Cases per strata
1.1	237	3154	355
1.2	124	1649	186
1.3	86	1146	129
1.5	56	741	83
1.8	38	511	58
2.0	33	434	49
2.5	25	328	37
3.0	21	274	31
4.0	16	217	24

RESULTS

Cohort study

In total, 661,474 patients with acceptable patient and general practice details were identified from the GPRD with at least one recorded prescription for an antidepressant. Of these, 294,229 were incident users aged 10 years or older and first treated with a single, study antidepressant. 158,530 of these patients had a medical diagnosis for depression or anxiety in the 18 months prior to the first antidepressant prescribing date.

Using the definition of exposure described, with time at risk starting one day after first prescribing on earliest date from the last day of follow-up, the date of a switch in treatment, or the date of the first suicidal behaviour, a total of 55,638 years at risk were considered, of which 34,147 were contributed by SSRI exposure (based on time to events after clinical review).

A total of 1693 incident suicidal events were identified from the GPRD, on or after the date of first prescribing, of which 1582 were subsequently confirmed following clinical review. Of the patients with first events that were reviewed but rejected, 5 were found to have a further, confirmed suicidal behaviours within their first antidepressant exposure, to give 1587 events confirmed by clinical review. Of these, 255 occurred on the date of first prescribing and were recoded as patient history. Subsequent suicidal events were found for 27 of these patients to give a final total of 1359 cases. In the case-control analysis, this event total was reduced to 1271 because of the inability to match some of the cases to an eligible control.

A list of all the events reviewed (both included and rejected from analysis) is given in [Appendix 5](#).

Patient demographic characteristics

In total, 93,305 of 158,530 patients received an SSRI as their first antidepressant treatment ([Table 1](#)). SSRI users were slightly younger than non-SSRI users ([Table 1](#)), although more than 95% of all SSRI and non-SSRI users were aged over 18. Approximately two-thirds of all incident users of both SSRIs and non-SSRIs were female, with more females among non-SSRI users. SSRI users were more likely to have a history of depression prior to initiation of therapy, and less likely to have prior anxiety alone. SSRI users also tended to be registered on the GPRD for longer periods prior to the first antidepressant prescription.

Of the patients first prescribed an SSRI, 30% received Paroxetine as their first treatment, 42% received Fluoxetine, 11% received Sertraline, 0.7% received Fluvoxamine and 16% received Citalopram/Escitalopram ([Table 2](#)). Although the large sample sizes suggested statistically significant differences between Paroxetine and other SSRIs in terms of age, gender, length of history and most recent diagnosis, there appeared to be few notable differences between products in the age or gender of patients at the time of first prescribing. Paroxetine and Citalopram users were more likely to have a history of anxiety prior to initiation of therapy relative to users of Fluoxetine, Sertraline or Fluvoxamine. Statistical comparisons also suggested statistically greater length of prior history among users of Paroxetine vs. other SSRIs.

Medical History at entry

Relative to non-SSRI users, SSRI users were more likely to have had a medical history of several factors related to an increased risk of suicidal behaviour. SSRI users were more likely to have had a psychiatric referral, prior suicidal behaviour, psychoses, acute cardiovascular disease, stroke, and less likely to have had a major life event recorded in the past 18 months, insomnia or epilepsy. ([Table 3a](#)). These patterns were more pronounced among patients 18 and under ([Table 3b](#)) in comparison to those over 18 ([Table 3c](#)).

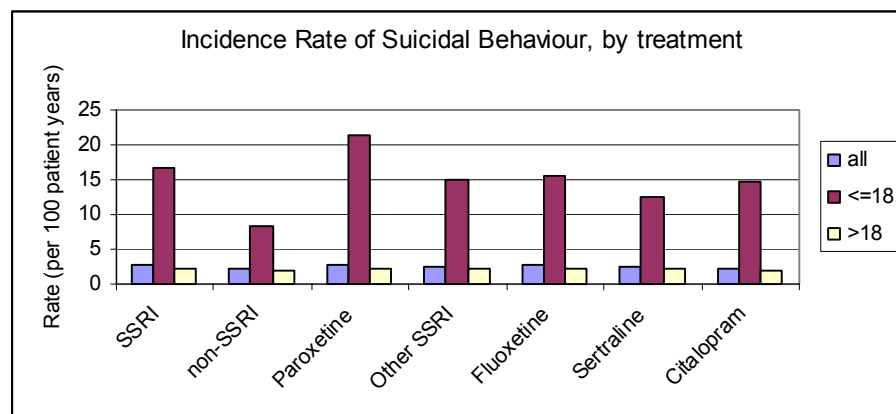

Insomnia and a history of prior psychiatric referral were the most common patient history events among users of Paroxetine and other SSRIs (Tables 4a). Relative to all other SSRI’s combined, Paroxetine users had increased prior history of psychiatric referral and a decreased history of psychoses, major life events, insomnia and multiple sclerosis. Relative to Fluoxetine, Paroxetine users were significantly more likely to have had prior psychiatric referral or insomnia, and significantly less likely to have had prior psychoses, multiple sclerosis or stroke (Table 4b). These patterns were more pronounced among patients aged 18 and under for both SSRI and Paroxetine users (Tables 4e and 4f) relative to the patterns observed in patients over 18 (Tables 4c and 4d).

Patients receiving SSRI’s and Paroxetine were more likely to have a prior history of psychiatric referral or hospitalization in all age groups (Table 5a). These differences were statistically different for all age groups of Paroxetine patients except 70-89 years and all age groups of all SSRI patients combined except for patients aged between 19-49 and over 90 years. Patients receiving SSRIs were significantly more likely to have a prior history of prior suicidal behaviour within the 10-18, 60-69 and 70-79 year age groups (Table 5b). Increased prior history of suicidal behaviour was also found among patients over 80 years old, although these differences were not statistically significant. A similar pattern was found for Paroxetine relative to all other SSRI users, but the differences between groups were not statistically significant.

Event Rate Comparison

Table 6a displays incidence rates of suicidal behaviours after initiation of therapy within treatment cohorts, for all patients, and by age and gender, based on suicidal events confirmed after clinical review. Crude and adjusted rate (hazard) ratios comparing groups are shown in Table 7a.

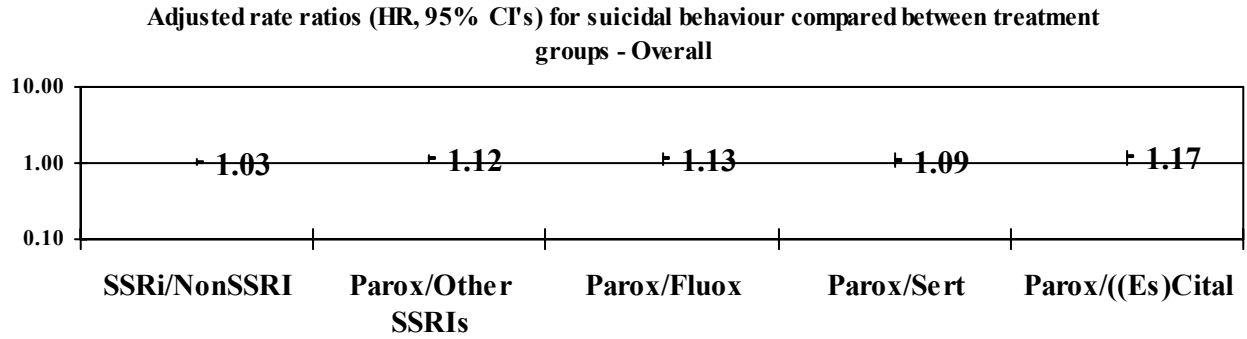

The crude incidence rates for SSRI, non- SSRI, Paroxetine, each individual SSRI (except Fluvoxamine) and all other SSRI users (except Paroxetine) combined are presented on the figure below.

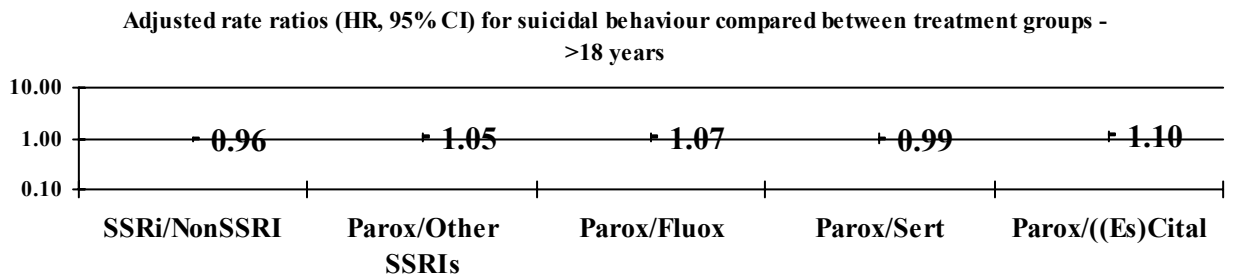

Unadjusted event rates were higher in all treatment cohorts among patients aged 18 and under (Table 6b) relative to those over 18 years (Table 6c). Male rates for those aged 18 and under (Table 6d) tended to be lower than those for women (Table 6f). By contrast,

event rates were generally higher for men over 18 years (Table 6e) relative to women over 18 years (Table 6g)

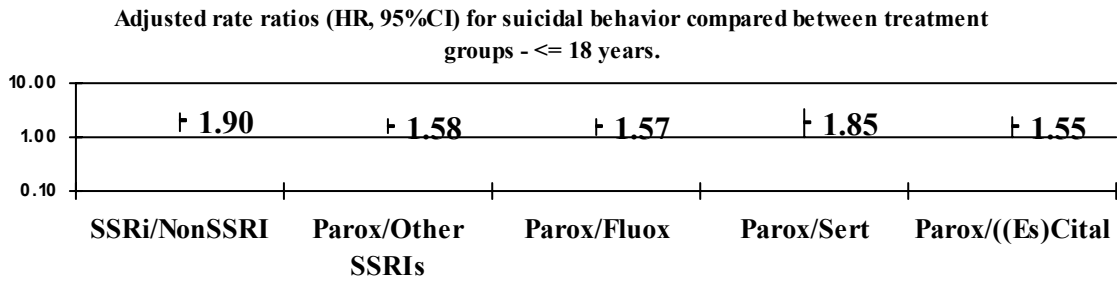

Overall, there was no statistically significant difference in the rates of suicidal behaviour for patients receiving SSRI's compared to users of non-SSRI's and Paroxetine users relative to other SSRI users (combined and individually) (Table 7a).

No statistically significant differences were found between SSRI and non-SSRI users or between users of Paroxetine and other SSRIs (individually or in aggregate), in adjusted analyses for patients aged over 18 (Table 7c).

For patients aged 18 and under, adjusted analyses suggested an statistically increased risk of suicidal behaviour for SSRI users relative to non SSRI users, and for users of Paroxetine against fluoxetine, sertraline and all SSRIs (excluding Paroxetine) combined (Table 7b).

Sub-group analyses

Sub-group analyses – by 10-year age groups

The incidence of suicidal behaviour was further investigated with the age groups 10-18, 19-29, 30-39, 40-49, 50-59, 60-69 and 70 years and older. We found the highest rates of suicidal behaviour, regardless of drug group, among patients aged 10-18 years old (Table 8a). The incidence rates of suicidal behaviour within these age groups for the study periods of initiation, maintenance and discontinuation are presented in Table 8b.

Rate of suicidal behaviour (per 100 patient years) by age and drug

After adjusting for prior history, we found no differences in the event rates among SSRI users relative to non-SSRI users and Paroxetine users relative to users of other SSRI's either individually or in aggregate, for patients 19 years and older (Table 9). We also found no significant difference in multivariate statistical models to evaluate the presence of a treatment by age interaction (Appendix 7).

Adjusted rate ratios (HR, 95%CI) comparing suicidal behaviour between SSRI/non-SSRI users by 10-year age categories

Adjusted rate ratios (HR, 95%CI) comparing suicidal behaviour between Paroxetine and other SSRI users by 10-year age categories

Sub-group analyses – by history of depression or anxiety

We investigated the potential for a different effect of SSRI and Paroxetine therapy on the risk of suicidal behaviour in patients aged 18 or under by their history of depression and/or anxiety. Incidence rates of suicidal behaviour in each drug group were generally highest in patients with either prior depression (Table 10a, 12a) or depression and anxiety (Table 11a) and lowest in patients with anxiety only (Table 13a).

After adjustment for patient demographics and prior medical history, suicide risk was significantly elevated among SSRI users relative to non-SSRI users among patients with a history of depression, in analyses considering depression only (HR=1.95, 95%CI=1.23-3.09) (Table 14), or all patients with depression (patients with depression alone or depression+anxiety, HR=1.90, 95%CI=1.26-2.86) (Table 16). Risk was elevated among patients with depression and anxiety together (HR=1.82, 95%CI=0.75-4.41) (Table 15) and with anxiety only (HR=2.01, 95%CI=0.54-7.45) (Table 17), but these estimates were not statistically elevated or statistically different from each other. However, the lack of a statistical increase in these estimates may be due to poor precision due to small sample sizes.

Suicide risk was also significantly elevated among Paroxetine users relative to all other SSRI users with a history of depression only (HR=1.78, 95%CI=1.25-2.52), but not among patients with history of only anxiety (HR=0.95, 95%CI=0.33-2.78) or depression and anxiety together (HR=1.17, 95%CI=0.57-2.42). The lack of precision in the estimates from the anxiety only patients may be due to small sample.

Similar trends were seen for Paroxetine relative to individual SSRI's. For patients with a history of depression and anxiety, the risk of suicidal behaviour was higher (HR=1.79, 95%CI=0.40-8.07) (Table 15) in the Paroxetine and Sertraline comparison than in the comparisons for Paroxetine with other individual SSRI's. This was not a statistically elevated increase and may be due to random variation resulting from the smaller sample of Sertraline patients observed in the study. The results of the comparison between Paroxetine and Fluvoxamine are not informative due to the small sample of Fluvoxamine.

All adjusted analyses were based on "full" models including all baseline variables from Tables 1 and 3.

Event type

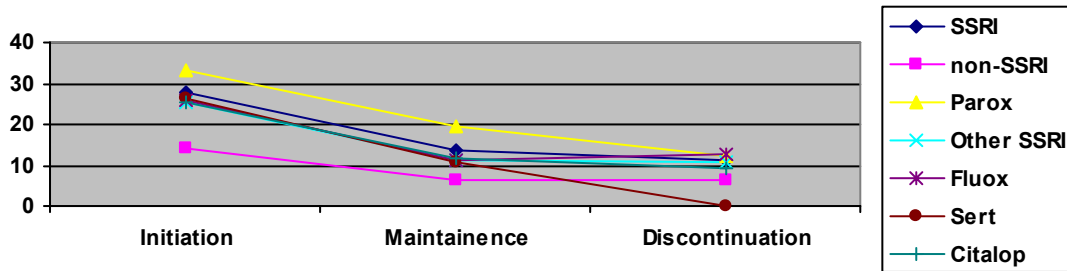

The majority of the events during exposure were classified as suicidal attempts (Table 18). Table 19 presents the progression of suicidal behaviour within the seven days following the first event. The results are intended to indicate whether the first event, as described, is likely to correspond to the initial stages of a more serious suicidal behaviour.

Of 1359 patients with a first events identified, 1160 (85%) had no additional suicidal records within the following seven days. Almost all the remaining patients had further records of the same event type as the initial event. It is unclear whether these records represented further independent behaviours, or additional records relating to the initial incident. However, these findings confirmed that the initial records were likely to represent accurately the type of behaviour. Only five patients were found to have progressed to a more serious outcome during the following week. Two patients progressed from ideations to suicide attempts, whilst a single patient progressed from ideation to a completed suicide. Two patients progressed from an attempt to a completed suicide. None of these patients was exposed to paroxetine.

Treatment effect stratified by period of use

Tables 20a, 21a and 22a present the event rates stratified by period of therapy (initiation, maintenance, discontinuation). Unadjusted event rates were highest in the 18 and under group, with the highest rate during initiation and the lowest in during discontinuation (Table 20b, 21b, 22b). Unadjusted rates among patients over 18 were also highest during the initiation period (Table 20c, 21c, 22c). This pattern continued across the 10-year age bands in patients over 18 (Table 8b).

Incidence rate of suicidal behaviour (per 100 patient years) by drug and period of therapy, for patients aged ≤18 yrs

Incidence rate of suicidal behaviour (per 100 patient years) by drug and period of therapy, for patients aged >18 years

After adjusting for prior history, stratification of these risk estimates by period of therapy (initiation, maintenance, discontinuation) demonstrated no effect due to duration of SSRI and Paroxetine therapy in adults (Table 23c, 24c, 25c). Patients using SSRIs were not at increased risk of suicidal behaviour relative to patients using non-SSRIs regardless of exposure period. A similar pattern was found for Paroxetine users relative to other SSRIs users combined and for Paroxetine relative to individual SSRIs.

We found that during the maintenance period, patients aged 18 years and under were at a significantly increased risk of suicidal behaviour associated with SSRI use relative to non-SSRI use (HR=2.08, 95%CI=1.07-4.04) (Table 24b) and with Paroxetine use relative to all other SSRI's combined (HR=2.15, 95%CI=1.36-3.4). Similar elevations were demonstrated for the comparison of Paroxetine relative to Fluoxetine, Sertraline and Citalopram (Table 24b).

The limitation of these analysis were that the maintenance period was highly variable between patients; 99% of patients entering the maintenance period had between 1 and 1037 days of maintenance therapy. As a result, the categorisation of the maintenance period was too broad to allow for an accurate investigation of the influence of duration. These analyses are potentially confounded by the large difference between the duration of maintenance period between different patients. This could not be addressed in this method of analyzing the cohort data, so adjustment for time since entry into the cohort was addressed within the nested case-control study.

Sensitivity Analyses

We also performed analyses which characterized events on the index date as possibly related to drug exposure (see [Appendix 2](#)). The number of cases on the index date considered as events does not have a direct mathematical relationship to the number of patients with prior history because many of the patients with events on the index date already had a history of suicidal behaviour before this point in time. The overall number of people in each drug cohort with prior history of suicidal behaviour was decreased but the pattern of differences were similar to those previously mentioned in this section. The event rates were increased but the pattern of differences between different treatment groups and patient sub –groups were similar to those presented in this section.

Nested case-control study

Demographic characteristics

The case-control analyses considering both SSRI and non-SSRI patients included 1271 cases, from the original sample of 1359. Analyses considering only SSRI users included 820 from 908 cases. Cases were excluded from these analyses when no appropriate match within the cohort could be found. In some instances, the inability to select appropriate controls resulted in a case being matched to fewer than four controls.

[Tables 26a](#) and [26b](#) describe the demographic and medical history characteristics of the cases and controls included in this analysis. Cases were different from the controls with respect to diagnosis of anxiety and/or depression prior to case-control index date, and insomnia, epilepsy, substance abuse, prior suicidal behaviour, major life events, psychiatric hospitalization and psychiatric referral.

Suicidal behaviour risk and prior drug use

[Table 27](#) describes the risk of suicidal behaviour in patients with a history of SSRI use relative to those with use of non-SSRI antidepressant. [Tables 28a-28e](#) provide similar analyses for Paroxetine use relative to all other SSRI use (combined and individually). These analyses determined the potential for age, duration, discontinuation, and both age and duration together to interact with treatment to increase the risk of suicidal behaviour. These are presented as estimates stratified into different population sub-groups. Each of these analyses should be considered separately because the presence of an interaction suggests that the relationship between treatment and risk of suicidal behaviour would be substantially different in different sub-groups of the population. However, our ability to detect an interaction with adequate statistical precision declines as we increase the number of potential interactions that are evaluated. As a result, for the higher order interaction (treatment by age and duration) we report the relative risk estimates in children for primarily descriptive purposes. A lack of a statistical difference in these

estimates may be attributable to either chance variation or lack of precision due to small sample sizes.

Overall, after adjusting for patient history, we found a non-significant decrease in the risk of suicidal behaviour associated with SSRI use relative to non-SSRI (OR=0.90, 95%CI=0.77-1.06). After adjusting for similar patient history factors, we found a small, non-significant increase in suicidal behaviour risk associated with Paroxetine use relative to other SSRI use (OR=1.13, 95%CI=0.93-1.38).

Sub-group analyses – interaction between drug used and patient age

We found no evidence of a trend by age associated with use of SSRI’s or Paroxetine in patients over 18 years old, in analyses considering age patients within 10 year age groups. Broadly, the results of these analyses were similar to the age-specific comparisons performed using the cohort data. We found no significant increase in risk associated with SSRI use relative to non-SSRI for any of the 10-year age groups except among patient 18 years and younger (OR=1.82, 95%CI=1.04-3.21) (Table 27).

We found no significant increase in risk associated with Paroxetine use relative to use of all other SSRI’s. We found both statistically non-significant elevations and decreases in risk associated with Paroxetine use relative to other SSRI use among different age groups, but the overall pattern was not suggestive of an increase or decrease associated with drug use at different ages (Table 28a). The greater risk associated with use in patients 70 and older is likely to be related to poor precision because this was the smallest age group of patients (~2% of cases and controls).

Adjusted relative risk of suicidal behaviour (OR, 95%CI) associated with Paroxetine relative to other SSRI use, by age group

Similar results were found for the comparison of Paroxetine and Fluoxetine use (Table 28b). A more pronounced age effect was present in the comparison of Paroxetine and Sertraline use. Paroxetine patients 10-18 years old were at a greater, but not statistically significant, increase in risk (OR=1.94) when compared to other age groups (OR=0.76-1.04) (Table 28c). The 70+ age group could not be described due to lack of sample in the Sertraline group.

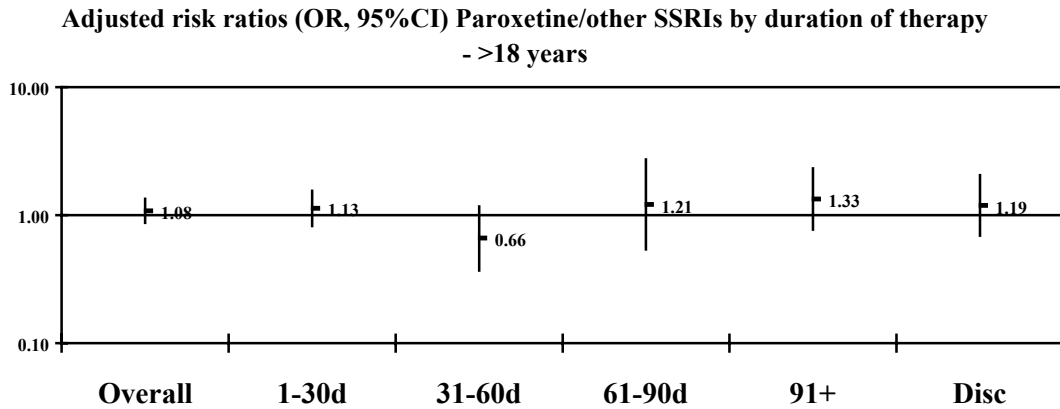

The comparison of Paroxetine use to Citalopram found age specific estimates that were considerably more variable than the comparison of Paroxetine to the other SSRI's (Table 28d). The increases observed in the 50-59 and 70+ age groups were likely to be related to random variation due to small sample rather than an increase due to differences in drug effect at these ages because few differences were seen in the 30-39, 40-49 and 50-59 year age groups. Among 10-18 year olds we found a non-significant increase in risk associated with Paroxetine use that was slightly higher (OR=1.58, 95%CI=0.84-2.96) than that observed with the comparison of Paroxetine use to all other SSRI use. We found a statistically significant increase (OR=2.02, 95%CI=1.15-3.54) among 19-29 year old patients. This is different from the cohort analyses where no increase was found. This relative risk estimate is not statistically different from the other age specific estimates. As a result, this is likely to be due to a combination of factors including sparse data, control selection and random variation.

Sub-group analyses – interaction between drug used, age and duration of therapy

Among adults, we found no significant interaction between suicidal behaviour, duration and treatment associated with SSRI use relative to non-SSRI use or Paroxetine use relative to use of all other SSRI's. In the same population, we also found no evidence of a trend of increased suicidal behaviour among SSRI users relative to non-SSRI users within increasing duration of therapy. We found similar results for the risk of suicidal behaviour associated with Paroxetine use relative to use of all other SSRI's.

Adjusted risk ratios (OR, 95%CI) SSRI/non-SSRI by duration of therapy - >18 years

Among patients 18 and younger, we found no significant interaction between suicidal behaviour risk, duration of therapy and SSRI use relative to non-SSRI use. We found increased risk with different durations of exposure but no trend associated with increasing duration of medication use: 1-30 days (OR=1.55) of 31-60 days (OR=3.24), 61-90 days (OR=1.52), 91+ days (OR=3.27). None of these estimates, with exception of the estimate for 31-60 days of exposure, were significantly greater than one or statistically different from each other. Given that this estimate occurred in the 31-60 day period and the estimate for the next period 61-90 days is considerable smaller (OR=1.52) it may be due to a combination small sample and an artefact of data reporting.

For patients 18 and younger, we found similar results for Paroxetine use relative to use of all other SSRI's. We found some evidence of a trend associated with increasing duration of therapy : 1-30 days (OR=1.11), 31-60 days (OR=1.51), and 61-90 days (OR=1.64), and 91+ days (OR=2.27). However, none of the estimates were statistically different from one or statistically different from each other; but this may have been attributable to lack of precision due to small sample size.

We found no statistically significant increased risk of suicidal behaviour associated with either SSRI or Paroxetine use during discontinuation (30 days after stop of therapy). Among adults the risk during discontinuation associated with SSRI use relative to non-SSRI (OR=0.93) was similar to the risk associated with Paroxetine use in comparison to other SSRI's (1.19). This trend was different in adolescents with a slightly lower risk during discontinuation with Paroxetine use (OR=1.44) in comparison to the risk associated with SSRI use (OR=1.68). However, none of the estimates from either set of analyses was statistically different from one or each other so this may represent differences due chance variation or poor precision due to sample size.

Tables 28b-e describe similar analyses of suicidal behaviour in patients with a history of Paroxetine use relative to those with using Fluoxetine, Sertraline or Citalopram. The risk of suicidal behaviour in Paroxetine users relative to Fluoxetine users was similar to the results obtained in the comparison of Paroxetine users relative to all other SSRI's because Fluoxetine users were the majority of the other SSRI users (Table 28a).

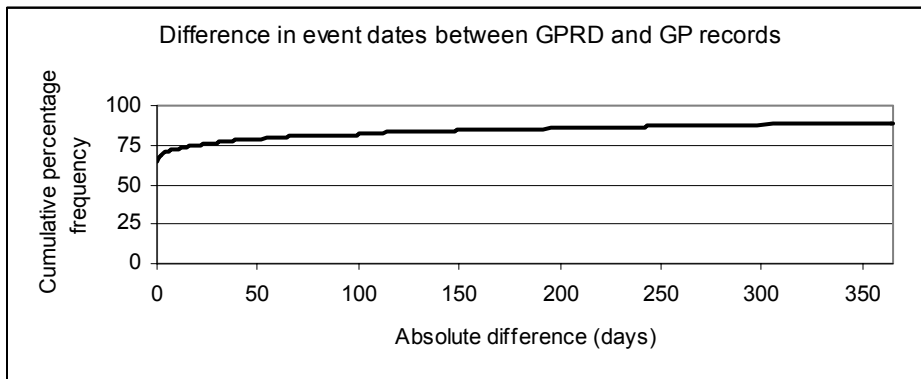

A similar pattern was also found in the comparison of Paroxetine use to Citalopram use (Table 28d) and Sertraline use (Table 28c). The results in both children and adults confirmed that duration of exposure did not appear to influence the relationship between drug use and risk of suicidal behaviour. The only exception was a statistically significant increase in the risk of suicidal behaviour among patients over 18 years in the comparison between Paroxetine and Citalopram use for patients with over 90 days of drug use (OR=3.08, 95%CI=1.12-8.42). This relative risk estimate was not-statistically different from the other age specific estimates. As a result, this was likely to be due to a combination of factors including sparse data, control selection and random variation.

Validation study results

In total, 1847 of 2260 questionnaires (82%) were returned to the MHRA. After exclusions due to missing and incorrectly filled out data, a total of 1801 questionnaires were included in all analyses. The results of our validation sub-study indicated a high level of agreement between the between GPRD records and GP recorded classifications of suicidal behaviour ever, and in the periods before and after first antidepressant prescribing (see table below). The kappa coefficient for suicidal behaviours before exposure of 0.72 indicated "good to excellent" agreement, and 0.64 after exposure, indicated "good" agreement. Although the overall chance corrected agreement was highest in analyses considering all time, the kappa coefficient of 0.46 only indicated "fair" agreement.

	Ever	Before index date	On or after index date
Observed agreement	0.85	0.87	0.83
Chance corrected agreement	0.72	0.54	0.52
kappa coefficient	0.46	0.72	0.64
Positive predictive value	84.0 (82.1, 85.7)	97.5 (97.0, 97.9)	78.8 (76.3, 81.1)
Sensitivity	99.1 (98.4, 99.5)	98.2 (97.8, 98.6)	93.5 (91.7, 94.9)
Specificity	37.7 (33.1, 42.6)	88.4 (86.4, 90.1)	69.0 (65.6, 72.1)

Overall, 64% of events agreed to the exact date, 72% matched to within 1 week and 77% matched to within one month.

DISCUSSION

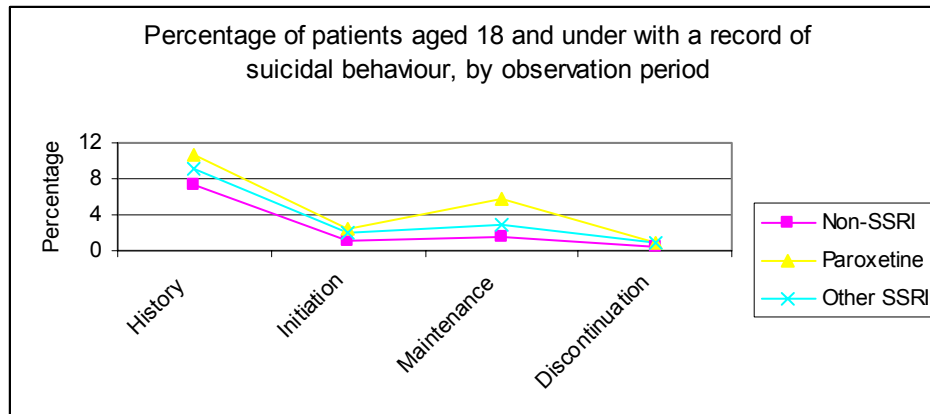

Our study found no increased risk of suicidal behaviour associated with use of SSRIs relative to non-SSRIs or Paroxetine relative to other SSRI's in adults. The increased risk of suicidal behaviour associated with use of SSRI and Paroxetine antidepressants was confined to adolescents (10-18 years). We found that this increased risk may differ by duration of SSRI use and Paroxetine use among children, but there was no trend associated with increasing duration of use among SSRI users relative to non-SSRI users. We found some evidence in both the cohort and case-control studies that, among children, the risk of suicidal behaviour may increase with increasing duration of exposure to Paroxetine relative to other SSRIs combined, although again, no statistically significant trends were apparent associated with increased duration of use with either SSRIs or Paroxetine among children.

In the cohort analyses, we found that Paroxetine users aged 18 and under were at an increased risk of suicidal behaviour relative to other SSRI users. However, these analyses were limited by their inability to control for any change in the patient's condition between the time of entry into the cohort and the time of the event and were unable to evaluate whether risk of suicidal behaviour was increased with longer duration of SSRI use.

In the nested case-control study we were able to address the limitations of the cohort study related to patient history and timing of therapy. Cases were matched to controls by age, gender, practice, duration of patient history in the database and time since first exposure. We then were able to evaluate the relationship between therapy and risk of suicidal behaviour stratified into the different patient sub-groups of age and duration of therapy. After controlling for the influence of the additional patient history information we found that risk of suicidal behaviour associated with use of SSRI's and Paroxetine was consistently elevated among those under the age of 18 years. None of these estimates were found to be statistically different from each other, although the small number of patients within sub-categories may have limited our ability to detect effects of the magnitude seen.

We made efforts to control for the potentially confounding influence of patient history factors which increase the risk of suicidal behaviour, but we acknowledge that patient psychiatric history is limited to GP information within the GRPD. Several types of major life events (bereavement, unemployment, divorce) in combination with other risk factors such as depression can lead to suicide¹³. Other known risk factors for suicidal behaviour include prior suicidal acts; family history of mental disorder or substance abuse; family history of suicide; family violence, including physical or sexual abuse; firearms in the home; incarceration; and exposure to the suicidal behaviour of others, including family members, peers, or even in the media.¹³ Also, there is evidence that alterations in neurotransmitters such as serotonin are associated with the risk for suicide.¹⁴ Diminished levels of this brain chemical have been found in patients with depression, impulsive disorders, a history of violent suicide attempts, and also in post-mortem brains of suicide victims.

We were unable to address any imbalances between study groups for such suicide risk factors as physical or sexual abuse, or a family history of suicide. Given the relatively small differences in event rates in the total sample after adjusting for the factors we could measure, and evidence that the treatment groups may have differed in baseline, it is possible that this increase may be attributable to confounding bias due to independent risk factors that we could not measure. As an illustration of this, the figure below presents the percentage of patients with records of suicidal behaviour before the start of therapy, and during the exposure periods of initiation, maintenance and discontinuation (from data within [Tables 3b, 20b, 21b and 22b](#)).

Although the percentages are based on different durations of follow-up within each period, it is clear that patients treated with non-SSRIs had the lowest levels of suicidal behaviour prior to initiation of therapy, and maintained the lowest levels throughout each period of exposure. SSRI users had higher levels of prior suicidal behaviour at baseline, and Paroxetine users had higher levels than users of other SSRIs. Again, these differences persisted throughout each period of follow-up. In addition, analyses of the event type indicated that the majority of the events were suicidal attempts, which suggested that we may have substantially underestimated the amount of prior suicidal thinking or ideation.

If we have been unable to account fully for any important differences in baseline risk of suicidal behaviour, these figures suggest that residual confounding will tend to overestimate the risk for users of SSRIs relative to users of non-SSRIs, and Paroxetine users compared to patients on other SSRIs. As a result, we conclude that children using SSRI medications may be at an increased risk of suicidal behaviour, and Paroxetine users may be at a slightly elevated risk relative to users of other SSRI medications. However, because these increases are relatively small, they may to be attributable to the unmeasured confounding by indication due to prescribing of SSRIs and Paroxetine to patients with an elevated background risk of suicidal behaviour.

Comparison to previous GSK research

The definition of suicidality applied to the GPRD appears to closely match that applied to other data sources within GSK. Searches of the GPRD have necessarily focused on coded records, rather than verbatim text searches. Nevertheless, the detailed coding dictionary available to physicians contributing to the GPRD means that a greater range of codes are available for coding suicidality and self harm than might be found in Meddra. Thus a more extensive "code" definition has been used for the GPRD database. All suicide and self harm related keywords applied to searches of the trial and spontaneous report data were used to construct the GPRD definition. The GPRD validation study suggested that few "true" records of suicidality were missed by the Medcode search alone.

The definition of events during exposure applied in this study (events on therapy or within the following 30 days), matches the definition used within the analyses of the paediatric clinical trial data.

The review of the paediatric trials data reviewed all "cause of death" records identified from a verbatim term search for suicidal keywords. A similar search was conducted by the GPRD division of the MHRA for patients within the analysis cohort, and all recorded identified in this way were included as potential events. It is likely therefore that the conclusion drawn from this study are based on a comparable definition of suicidality as used by previous work within GSK.

Comparison to previous external research

Clinical depression is a major public health problem that can lead someone to suicidal behaviour (i.e. ideation, attempts, and completed suicide). There is a considerable body of population research that has shown major depression increases the risk of suicidal behaviour compared to people without depression⁶⁻⁹. Depressed patients have been found to have a 25-fold greater risk of suicide than those not depressed¹⁰. Research has shown that more than 90 percent of people who kill themselves have depression or another diagnosable mental or substance abuse disorder, often in combination with other disorders.¹¹ Additionally, the risk of death by suicide is believed to be related to the *severity* of depression. Those treated for depression as inpatients following suicidal ideation or suicide attempts have been found to be three times as likely to die by suicide as those who were only treated as outpatients¹².

Much less is known about the risk of suicide among those suffering with anxiety disorders, and most research has been conducted in those aged 18 and under. An investigation of 348 adolescent psychiatric inpatients found that the rate of attempted suicide was much lower in OCD patients, as compared to other mental disorders, and that there was an inverse relationship between depression and suicidality in these patients²⁹. OCD and SAD were not found to be associated with suicidality in a sample of 1,979 adolescents referred to a general clinic³⁰. Therefore, the relationship between anxiety disorder such as OCD or SAD and suicidality is largely unknown at this time

Suicidal behaviour is a complex condition with several components (suicidal ideation, attempt and completion) which vary with age, gender and ethnicity, and may even change over time. U.S. males are 4 times more likely to complete suicide than females, while females report attempting suicide 2 to 3 times more often than males¹³.

Among age groups in the United States, the elderly, adolescents and young adults have the highest rates of completed suicide¹². According to the U.S. Surgeon General, for young people aged 15-24 years old, suicide is the third leading cause of death, behind unintentional injury and homicide¹⁵. The rate of completed suicide appears to increase throughout adolescence and young adulthood. For children aged 10-14, the rate was 1.6/100,000 persons, the rate for children aged 15-19 was 9.7 per 100,000, and the rate for young people aged 20-24 was 14.5/100,000¹⁵.

Non-fatal suicidal behaviour differs by gender and ethnicity among young adults. The 1997 Youth Risk Behaviour Surveillance System found that Hispanics (10.7%) were significantly more likely than white students (6.3%) to have reported a suicide attempt. Among Hispanic students, females (14.9%) were more than twice as likely as males (7.2%) to have reported a suicide attempt, while Hispanic male students (7.2%) were significantly more likely than white male students (3.2%) to report this behaviour (15).

Similar to the Youth Risk Behaviour Surveillance system study, we found that adolescent females tended to have higher rates of suicidal behaviour. We also found event rates in adolescents ranging from 3-15/100 person-years among males and ranging from 11-30/100 person-years among females aged 10-18 years inclusive (Tables 6d, 6f). The rates from our study were generally higher than seen above, but may be related to the increased risk of suicidal behaviour for people with depression, or depression and anxiety, relative to the general population.

We found that adults had lower rates of suicidal behaviour than children and that men tended to have higher rates of suicidal behaviour relative to women. National estimates of suicidal behaviour are not available for the UK or other European countries. The WHO/EURO Multicentre study on parasuicide estimated the average prevalence of suicidal attempts (parasuicide) in 1992 across 16 European centres among people 15 years and older as being higher in women (165/100,000) relative to men (130/100,000) (32). The 12 month incidence and prevalence of suicidal ideation has been reported from a follow-up study of adults aged 24-64 in Finland (33). In contrast to other countries, the overall prevalence of suicidal ideation in the Finnish study was higher in men (14.7%) relative to women (9.2%) and decreased with age. The incidence of suicidal ideation was also higher in men (4.6%) than women (3.1%). This is similar to the range of annual

incidence rates that we found in men (3.05-4.47%) but was a little higher than that of women in our study (1.38-4.47).

The General Practice Research Database has previously been used to investigate the association between suicide and the use of antidepressant medications. Jick et al (26) identified a cohort of 172,598 antidepressant medication users in the database (1988-1993) and performed a nested control study to control for confounding factors. They found a higher rate of suicide in men relative to women and found that fluoxetine had the highest rate of suicide for the ten antidepressants studied. They also found that suicide rates were higher in the first 30 days after the last prescription than in the period 31 to 180 days after the last prescription. After controlling for age, gender and calendar year and restricting to patients without a history of suicidal behaviour, they found that the adjusted risk of suicide associated with fluoxetine use relative to other medications was lower (OR=2.1, 95%CI=0.6-7.9) relative to the total population (OR=3.8, 95%CI=1.7-8.6). They concluded that, however, that the effect of fluoxetine may have been explained by selection bias leading to a higher background risk of suicide in the fluoxetine users.

Recently this work has been updated by Jick, Kaye and Jick (39) using patients identified from 1993-1999 from the older VAMP version of the GPRD. This study was a case-control study of non-fatal suicidal behaviour (attempts and ideation) and suicide to investigate the risk of these events associated with use of Paroxetine, fluoxetine and amitriptyline relative to use of dothiepin. Cases were matched to controls by age, sex, duration of history in the GPRD, general practice and index date. They found that Paroxetine was associated with a small, but not statistically increased risk of non-fatal suicidal behaviour (OR=1.29, 95%CI=0.97-1.70). Among 10-19 year olds, they found a small, but not statistically increased risk of non-fatal suicidal behaviour associated with Paroxetine use (OR=1.7, 95%CI=0.7-4.1). They concluded that the small increase in risk they found was likely to be attributable to uncontrolled confounding.

Both of these results are comparable to the results of our comparison of Paroxetine use to use of all other SSRI's combined for both the total sample (OR=1.13, 95%CI=0.93, 1.38) and children aged 10-18 (OR=1.39, 95%CI=0.89,2.16). They are also comparable to our results for the comparison of SSRI use relative to non-SSRI use for both the total sample (OR=0.90, 95%CI=0.77, 1.06) and children age 10-18 (OR=1.82, 1.04, 3.21). Our finding of this significant difference among children may be attributable to the larger sample size and broader range of non-SSRI medication that we included in our study population. They found no interaction by age or gender, but did not investigate the presence of an interaction between risk of suicidal behaviour, treatment type and duration of therapy.

Our study was conducted independently of their study. Their sample was drawn from a restricted set of practices and an older version of the database that did not include the same sample of patients included in the newer version of the GPRD. As a result, this is the first example to our knowledge where two independent research groups have performed similar investigations in both the old and new versions of the GPRD and obtained similar results.

Limitations

The use of an electronic database has several potential limitations in the study of suicidality and antidepressant use.

The validation study demonstrated that our use of the database information to identify cases may have overestimated suicidal behaviour present within the consulting population. Of particular concern is the potential for events coded as over-dose to be related to something other than suicidal intent. In those cases where we had no other information, we assumed that the event was an attempt. Cases of overdose and any other type of suicidal behaviour, with multiple sources of information, were reviewed by two independent clinicians with UK practice experience to assign the case status. As a result our rates might be higher than other research using a more restrictive definition of suicidal behaviour, although this is unlikely to affect the pattern of differences that we observed.

We have assumed that the date of suicidal behaviour is correct in the GPRD for the purposes of assignment of an event to a specific point in time. A major potential limitation of incorrect date assignment would be if events occurring after treatment initiation were misclassified into the period of prior history. This would tend to reduce the event rates we measured. However, the validation study indicated a relatively strong concordance between GPRD and GP event date assignment. We also found that the accuracy of classification of events occurring before and after the date of treatment initiation appeared to be similar. Even if some suicidal behaviour event dates were misclassified, we had no reason to suspect this was occurring more commonly among one drug group relative to another. As a result, we would not expect the pattern of differences in suicidal behaviour risk that we found to be substantially affected.

The patients in our study were selectively drawn from people with a recent depression or anxiety diagnosis and were not previously treated with antidepressant medication. They would be expected to have a higher rate of suicidal behaviour than the general population but would not be representative of the total population of people with depression or anxiety treated with antidepressant medication. People with multiple medications or initiating repeat therapy were excluded to reduce the possibility of that the patients included in the study were those who were less likely to exhibit suicidal behaviour with a given type of medication due to previous positive experience with that therapy. Although this reduces the generalisability of our event rates to the total UK population, it increases the likelihood that our findings of a small or non-existent treatment effect in adults was related to the lack of a treatment effect.

However, the GPRD database represents those that have sought and received treatment for depression, OCD, GAD, SAD, suicidal behaviour, and the other medical conditions that we are evaluating. Previous research indicates that only a minority of people who have long-term suicidal ideation seek professional help for psychiatric reasons(6) In our study, it was possible the type of patient that is likely to seek care for suicidal behaviour is distinctly different from those that do not present to the GP. The potential influence would be an increased tendency of these patients to report suicidal behaviour to their GP's. If this increased reporting was not associated with use of any particular drug it

could have increased the rates of events we measured but would not have increased the differences we observed between the medication groups. Given the media attention given to the possible link between SSRI use and suicide, it is possible that these patients were more likely to report suicidal behaviour because of concern over a possible adverse drug effect. We tried to adjust for this imbalance by controlling for past suicide behaviour. However, as discussed above, it is likely that all information relating to the background risk of will not be recorded on the GPRD. It should also be noted that the most commonly reported suicidal behaviour identified in this study was attempted suicide, rather than suicidal ideation as may have been expected. This suggests that suicidal ideation may not be well recorded on the GPRD even among patients reporting for care, and undetected differences in baseline suicidal risk may remain between treatment groups, providing further evidence for the potential for uncontrolled confounding. The possible effect of this bias would be a spuriously elevated association between SSRIs and risk of suicidal behaviour.

We investigated for the presence of a biasing effect of a case diagnosis date in 2000-2003 when the media coverage on the recognition of suicidality associated with drug use was likely to have been strongest. We found that controlling for this variable in our analyses did not influence the results from our case control study. Although these results suggested that bias due to case diagnosis date was not a significant influence, we cannot rule out a possible differential influence in our results due to other factors that may have increased recognition among the Paroxetine group but were not associated with specific year of diagnosis.

One of the major benefits of the GPRD is the ability to link events and drug exposure by time. This allows for the construction of case-control studies that are not biased due to better recall of treatment history among patients with more severe disease. Despite this advantage, control selection with the GPRD can introduce bias into the study results if the controls selected do not accurately represent the true population base from which the cases were drawn. We substantially reduced the possibility of non-representative controls by selecting both cases and controls from patients treated with antidepressants rather than from the general population. We also matched cases to all potential controls available at the time of case occurrence. This method of matching to the risk set further eliminated the possibility of non-representative controls. The trade off for the use of this method was the potential for a error in the measurement of the variance which could have resulted in the finding of a statistically significant difference when one was actually not present. Given the sample size, this effect was likely to be very small but we felt more comfortable taking an approach that was likely to be closely aligned with the values of public health surveillance activities.

Finally, although we had a very large number of patients in most of our drug groups, for some of the sub-group analyses that we presented, the sample size was insufficient to detect a statistically significant difference if one was present. This is likely to have been a problem in some of the comparison between drugs that we performed for those patients aged 18 and under between Paroxetine users and users of other drugs given to a small number of people (i.e. Fluvoxamine). In these cases the presence of an elevated relative risk estimate ($OR > 1$) with a 95% confidence interval containing the value one would indicate that an increased risk may be present but could not be measured due to small

sample size. For the majority of our comparisons we had sufficient sample size to detect a statistical difference if one was present. It should be noted, however, that no attempts have been made to consider the issue of multiple testing within this study. We did not consider it appropriate to apply any additional constraints that might have limited our ability to detect safety signal in a study considering a major public health question. However, the disadvantage of this approach is that we may have highlighted spurious associations. Additionally, many of the analyses presented are discussed descriptively, without reference to formal statistical significance. These points should be noted when considering individual comparisons, and the study as a whole.

CONCLUSION

Our study found no increased risk of suicidal behaviour associated with adult use of SSRI's relative to non-SSRI use or Paroxetine use relative to use of other SSRI's. The increased risk of suicidal behaviour associated with use of SSRI and Paroxetine antidepressants was confined to adolescents (10-18 years). We also found that this increased risk may differ by duration of SSRI use and Paroxetine use but there was no significant trend associated with increasing duration of use among children. As a result, we conclude that children using SSRI medications may be at an increased risk of suicidal behaviour, and paroxetine users may be at a slightly elevated risk relative to users of other SSRI medications. However, because these increases are relatively small, they may be attributable to the unmeasured confounding by indication due to prescribing of SSRI's and Paroxetine to patients with an elevated background risk of suicidal behaviour.

ACKNOWLEDGEMENTS

We would like to thank (name deleted), Consultant Psychiatrist, for undertaking the clinical review of potential suicidal events, and (name deleted) for additional SAS programming.

Appendix 2 . Cohort analysis with cases including events on index date

Events on date of first treatment are considered to be events during follow-up. Table numbers reflect the sequence in Appendix 1. All analyses have not been repeated with cases on the index date included.

Table 3a. Medical History for those newly prescribed SSRI vs. Non-SSRI. All figures are based on details on the date of first antidepressant prescription.

Medical Event	SSRI n (%)	Non-SSRI n (%)	Crude Odds ratio	Adjusted Odds ratio
prior suicidal event	4479 (4.8)	2725 (4.18)	1.16 (1.1-1.21)	1.04 (0.99-1.09)

Paroxetine vs. Fluvoxamine (reference)	0.19 (0.02-1.49)	0.18 (0.02-1.64)
Paroxetine vs. Citalopram (reference)	1.27 (0.38-4.22)	1.21 (0.36-4.14)

Table 25c. Incidence rate ratios for Suicidal Events during the discontinuation period. Analyses include all patients aged Over 18 and consider the first event only (all event types combined).

Comparison	Crude (unadjusted) hazard ratio (95% CI)	Adjusted hazard ratio (95% CI).
SSRIs vs. Non-SSRIs (reference)	1.08 (0.81-1.45)	0.93 (0.69-1.25)
Paroxetine vs. all other SSRIs (reference)	0.97 (0.65-1.46)	0.98 (0.65-1.48)
Paroxetine vs. Fluoxetine (reference)	1 (0.64-1.56)	1.06 (0.67-1.66)
Paroxetine vs. Sertraline (reference)	1.07 (0.54-2.13)	1.02 (0.52-2.04)
Paroxetine vs. Fluvoxamine (reference)	0.79 (0.11-5.77)	0.64 (0.09-4.7)
Paroxetine vs. Citalopram (reference)	0.85 (0.48-1.5)	0.82 (0.46-1.44)

Appendix 3. Suicidal Behaviour Definition

The code list below provides details of the final definition of suicidal behaviour and self harm used to select potential events on the GPRD. The list of GPRD medical codes to define suicidal behaviour was developed in the following steps:

1. An initial search of GPRD MEDCODE descriptions was conducted using a list of suicide keywords. This keyword list was based on the terms used by clinical investigators on the case report forms (CRF) in GSK Paroxetine clinical trials. Potential codes were selected where the GPRD text description contained any of the following text strings: "angry", "attempt", "attempted suicide", "cut", "deliberate", "drug overdose", "gas", "hang", "hung", "idea", "intent", "jump", "mutilat", "overdos", "parasuicide", "plan", "self", "self damag", "self harm", "self inflict", "shoot", "slash", "suic", "suic", "suicidal ideation", "suicidal plans", "suicidal thoughts", "tende", "think", "thought", "threat", "viol", "wish". All searches were conducted to allow codes to be identified if the text string appeared anywhere in the text description. Searches for multiple words identified a match if the words appeared in any order, so "self harm" would return matches on "self harm", "self-harm", "harm self", "harm to self" etc.
2. Any codes that were clearly not related to suicidal behaviour were removed from the initial list after clinical review, and the remaining preliminary group of Medical Codes were used to identify potential suicidal events from our study cohorts. A sample of records related to these suicide Medical Codes, were sent to the MHRA to obtain the anonymised free text comments related to these events. These Medical Codes underwent internal clinical review whereby each code was evaluated based upon the code itself, and and free text comments used with it. Additions were made to the initial list of suicide keywords based upon terms that were seen in the GPRD free text comments.
3. Where required, for a final clinical decision on the validity of each potential suicide code, a random sample of 3 complete patient histories, per code, were extracted and reviewed by an internal GSK physician. Review was intended to determine if anything in the free text comments *globally* contradicted the code description.
4. The final review process included full, independent clinical review by clinicians within Epidemiology and elsewhere within GSK.

The codes included in the final list, after review, are given below.

<u>GPRD Medical Code</u>	<u>GPRD Medical Code Text Description</u>
228088	[X]ATTEMPTED SUICIDE
291992	[X]DELIBERATE DRUG OVERDOSE / OTHER POISONING
273848	[X]DELIBERATE DRUG POISONING
228087	[X]INJURY - SELF-INFLICTED

264657	[X]INT SELF HARM BY JUMP FROM HIGH PLACE INDUST/CONSTR AREA
255489	[X]INT SELF HARM BY JUMP FROM HIGH PLACE OCC OTH SPECIF PLCE
282896	[X]INT SELF HARM BY JUMP FROM HIGH PLACE OCC UNSPECIF PLACE
273842	[X]INT SELF HARM BY STEAM HOT VAPOR/OBJ SCH/INS/PUB ADM AREA

Identification of suicidal events from the free text associated with Death records

To ensure that records of completed suicide were identified where the event was coded using a non-specific death code, the free text of all death records for patients in the final cohort were searched for suicide related keywords. Records identified in this way were then subject to the full process of review as potential events.

All searches were conducted to identify both upper and lower case text. Searches specifying that a keyword can appear “anywhere” in the free text identified comments starting or ending with the specified keyword. Searches using the logical <AND> identified comments containing each word, irrespective of the order in which these keywords appear

Keywords used in search of the free text associated with death records

The term <AND> used throughout the text only refers to the logical operator AND, not to a keyword to be searched for.

- SUICID - Appears anywhere in free text field
- OVERDOS - Appears anywhere in free text field
- DEATH - Appears anywhere in free text field
- DEAD - Appears anywhere in free text field
- DIE; WANT - The words WANT <AND> DIE both appear anywhere in the free text field, not necessarily consecutively
- DIE; WANTED - The words WANTED <AND> DIE both appear anywhere in the free text field, not necessarily consecutively
- DIE; WANTED - The words WANTED <AND> DIE both appear anywhere in the free text field, not necessarily consecutively
- DIED; WANTED - The words WANTED <AND> DIED both appear anywhere in the free text field, not necessarily consecutively
- MORBID - Appears anywhere in the free text field (but not as part of the word COMORBID/COMORBIDITY)
- DYING - Appears anywhere in the free text field
- END; LIFE - The words END <AND> LIFE both appear anywhere in the free text field, not necessarily consecutively (Note: ENDING should appear as ENDING, not as part of a word such as BENDING, MENDING etc.)
- ENDING; LIFE - The words ENDING <AND> LIFE both appear anywhere in the free text field, not necessarily consecutively (Note: ENDING should appear as ENDING, not as part of a word such as BENDING, MENDING etc.)
- ENDED; LIFE - The words ENDED <AND> LIFE both appear anywhere in the free text field, not necessarily consecutively (Note: ENDED should appear as ENDED, not as part of a word such as BENDED, MENDED etc.)
- ENDS; LIFE - The words ENDS <AND> LIFE both appear anywhere

in the free text field, not necessarily consecutively
(Note: ENDS should appear as ENDS, not as part of a word such as BENDS, MENDS etc.)

- END; ALL - The words END <AND> ALL both appear anywhere in the free text field, not necessarily consecutively (Note: END should appear as END, not as part of a word such as BEND, MEND etc.)
- ENDING; ALL - The words ENDING <AND> ALL both appear anywhere in the free text field, not necessarily consecutively (Note: ENDING should appear as ENDING, not as part of a word such as BENDING, MENDING etc.)
- ENDED; ALL - The words ENDED <AND> ALL both appear anywhere in the free text field, not necessarily consecutively (Note: ENDED should appear as ENDED, not as part of a word such as BENDED, MENDED etc.)
- ENDS; ALL - The words ENDS <AND> ALL both appear anywhere in the free text field, not necessarily consecutively (Note: ENDS should appear as ENDS, not as part of a word such as BENDS, MENDS etc.)
- KILL; SELF - The words KILL <AND> SELF both appear anywhere in the free text field, not necessarily consecutively
- LIVE; WANT; NOT - The words NOT <AND> WANT <AND> LIVE all appear anywhere in the free text field, not necessarily consecutively (Note: LIVE should appear as LIVE but not as LIVER etc.)
- LIVING; WANT; - NOT The words NOT <AND> WANT <AND> LIVING all appear anywhere in the free text field, not necessarily consecutively
- ALIVE; WANT; NOT - The words NOT <AND> WANT <AND> ALIVE all appear anywhere in the free text field, not necessarily consecutively
- LEAVE; WORLD - The words LEAVE <AND> WORLD both appear anywhere in the free text field, not necessarily consecutively
- GAS - Appears anywhere in the free text field
- GASSED - Appears anywhere in the free text field
- HANG - Appears anywhere in the free text field
- HUNG - Appears anywhere in the free text field
- JUMP - Appears anywhere in the free text field
- JUMPED - Appears anywhere in the free text field
- SHOOT - Appears anywhere in the free text field
- SHOT - Appears anywhere in the free text field
- SLASH - Appears anywhere in the free text field
- SLASHED - Appears anywhere in the free text field
- SLASHING - Appears anywhere in the free text field
- CUT - Appears anywhere in the free text field
- CUTTING - Appears anywhere in the free text field

- SELF; INFLICT - The words SELF <AND> INFLICT both appear anywhere in the free text field, not necessarily consecutively
- SELF; DAMAG - The words SELF <AND> DAMAG both appear anywhere in the free text field, not necessarily consecutively
- SELF; VIOL - The words SELF <AND> VIOL both appear anywhere in the free text field, not necessarily consecutively
- MUTILAT; SELF - The words SELF <AND> MUTILAT both appear anywhere in the free text field, not necessarily consecutively
- HARM; SELF - The words SELF <AND> HARM both appear anywhere in the free text field, not necessarily consecutively.

The GPRD medical codes defining a death record, as supplied by the MHRA GPRD Division, are given below, are given below.

GPRD medical code	Code Text Description
232865	SD17/18 cause of death NOS
226667	[D]Instantaneous death
232864	Hospital death discharge notif
230556	Death
227366	Killed by rolling stock - other specified person
236409	Killed by rolling stock - pedal cyclist
300566	Killed by rolling stock - railway employee
296898	Death administration
246910	VIOLENT DEATH
296484	Preoperative anaesthetic death
245503	Found dead on railway unspecified - passenger
245500	Killed by rolling stock
244770	[D]Sudden death, cause unknown NOS
244769	[D]Death less than 24 hours from onset of illness NOS
241921	Cause of death
241920	Patient for cremation
235749	[D]Died, with no sign of disease
241918	Death cert. Med A signed
232866	Patient died in publ.place NOS
239551	O/E - dead - expected
237692	DEATH

296899	Stat B,C and F cremation certs
296900	Patient died in place NOS
296901	Referral to coroner
299833	[D]Death less than 24 hours from onset of illness
235750	[D]Unattended death
223735	Patient died in hospice
232867	Death administration NOS
241919	SD17/18-no details, returned
208564	[D]Found dead
221486	O/E - dead NOS
210633	SUDDEN DEATH
301899	POST MORTEM REPORT RECEIVED
302004	DIED
305432	SUDDEN DEATH NONVIOLENT
305437	FOUND DEAD
305438	UNKNOWN CAUSE DEATH
214702	Death certificate form Med A
209256	Killed by rolling stock - pedestrian
214703	Report for Coroner NOS
208562	[D]Mortality, cause unsure
205712	Crem. Form part C completed
205711	Ask for hosp death disch lett.
205710	Med A given to family
205709	Death cert. Med A due
203432	O/E - death rattle
203428	Patient died
209258	Found dead on railway unspecified - other spec person
214711	Post mortem report received
223733	Cremation certification
223732	Hospital death disch. NOS
223731	Coroner's post-mortem report
223678	Death in hospital
219554	CORONER REFERRED TO
248767	O/E - dead
218674	Accidentally killed NOS
212395	Died
217544	[D]Death, not instantaneous cause unknown
223734	Dead on arrival at hospital
214710	Place of death
214709	Patient died - to record place
214708	Cremation certification NOS
214707	Crem. Form part C arranged
214706	Cause of death clarif. SD17/18
214705	Death notif. From hospital
214704	Coroner's PM report NOS
217555	[X]Ill-defined and unknown causes of mortality

260296	Patient died in nursing home
260290	Coroner report - requested
294585	O/E - dead - condition fatal
283173	[V]Issue of death certificate
248768	O/E - dead - unattended death
260299	Post mortem report
291278	Killed by rolling stock - unspecified person
260297	Unexpected death-Coroner told
290575	[X]Other sudden death, cause unknown
260295	Died - place patient died
260294	Deceased - place patient died
260293	SD18 - cause of death clarif
260292	Receiv hosp death disch letter
260291	Coroner report - paid for
272402	[X]Other ill-defined and unspecified causes of death
260298	Condition fatal-cause of death
287729	Med A not signed-coroner case
273081	Found dead on railway unspecified - unspecified person
269510	Patient died in hospital
269509	Crem. Form part B completed
269465	Died in hospital
267185	O/E - dead - unexpected
291285	Found dead on railway unspecified - pedestrian
287730	Dead - place patient died
285439	O/E - dead - suspicious death
284701	DROPPED DEAD
283503	DEATH IN HOSPITAL
289080	Sudden cardiac death, so described
283395	REPORT RECEIVED FROM CORONER
290566	[D]Found after death, unknown cause of death
287731	Patient died at home
281406	[D]Sudden death, cause unknown
248769	O/E - dead - sudden death

253824	Fetus or neonate affected by maternal death

Appendix 4. Assignment of concomitant medications and co-morbid conditions.

Final list of GPRD antidepressant codes.

All products are considered as study drugs, except those indicated as exclusion criteria. Prescriptions for ‘exclusion’ drugs were examined to ensure that all patients were exposed to a single, study drug on the date of first treatment. Excluded products were also considered to determine any changes in treatment (see Methods).

gprd_product_code	description	antidepressant_class	ssri_type	product_name
4006235	DEPIXOL -CONC injection 100mg/ml	Exclusion Criteria		FLUPENTHIXOL

168825	Fluoxetine	24/01/2003	24/01/2003	Clinical	212349	SUICIDAL IDEATION	and depressive episode. Has been coming on for a few months. Has relationship issues. Is with a new woman. Both he, and his girlfriend are both married. He has an issue with her being married, but doesn't know why. Low mood, tearful all the time, and very much so during consultation. Just got a new job last week. Became violent last night. Constantly arguing with his girlfriend. Hasn't hit her, but bashed a couple of doors off their hinges. Has felt suicidal for 2 days. Has been thinking through how to do it. Has an undrivable car with no brakes, and has been cutting himself superficially last night. Has been wandering around town aimlessly. Poor sleep pattern. In the long term he needs counselling to try and resolve issues. Fluoxetine started today. I'm not happy that he won't be a risk to himself and others over the weekend --> urgent CMHT referral made over the phone for assessment today -- accepted. To review him here again early next week.

298042	Citalopram	23/12/1998	04/01/1999	Clinical	209082	OVERDOSE OF DRUG	<p>-----</p> <p>was referred to the Centre by Dr. ----- following a serious suicide attempt, an overdose of 150 Paracetamol tablets. She spent six days in ----- Hospital before admission to ----- Hospital where she remained for five weeks. Dr. ----- diagnosis is that of personality disorder and depressive illness. On assessment she presented as a rather sullen girl and throughout the interview her mood was rather flat. She has a history of self harming and has many visible marks, some fairly recent superficial lacerations. She disclosed her family history culminating in her talking about her relationship with her father which she states is not very good, she believes that he and his partner get at her for no good reason. She stated that she had taken the overdose because she could no longer cope. On discharge from ----- ----- Dr. ----- referred her to the Department of Psychological Therapies for individual and family therapy. She was allocated ----- C</p>

1875556	Paroxetine	04/10/2001	07/11/2001	Clinical	209082	OVERDOSE OF DRUG	:~~~~~ - Dob: ~~~ 83 ~~~~~ ~~~~~ Emergency Dept This 18 year old gentleman presented to the Emergency Department at ~~~~~ on the 5th November 2001. He had taken a deliberate overdose of 9 Diazepam 5mg and 1 Zopiclone tablet without paracetamol or alcohol. The action was an impulsive act, he was in his car alone and had pulled to the side of the road and taken the tablets. He drove to his girlfriend soon after. He stated that he wanted to die at the time and he didn't know whether he would do it again. I note his background of a worsening mental state in the past six weeks, no previous history of overdose or alcohol excess but recent loss of job. I note that you have recently prescribed him Paroxetine for depression. In the department he was anxious and low with a flat affect but no abnormal perceptions. Physical examination was unremarkable and an ECG and base line bloods showed no cause for concern. After discussion with his girlfriend and his parents he was advised to ret

1882617	Citalopram	30/06/2003	08/07/2003	Clinical	209082	OVERDOSE OF DRUG	<p>Dear Dr ----- D o B -----,74 ----- Thank you for your referral of this young lady whom I saw at outpatient clinic today 8th July 2003. ----- told me that she took an overdose of Co-dydramol tablets in May this year. She said she was feeling very depressed and felt overwhelmed. On enquiry she told me apparent precipitant was the separation from her husband after 2 years. He is the father of their only child, a son aged ---- years who now lives with her. Her ex- husband has also started a restaurant business together with the financial involvement of her parents. Since her separation from her husband her parents are now left with running the business on their own. She feels quite guilty about this and believes that the business will be sold shortly. At the time of the overdose she said that she was also particularly distressed by having to work 2 jobs, that of her support work of children with emotional and behavioural</p>

							difficulties during the day and working in the restaurant at

1917996	Citalopram	15/11/2000	20/11/2000	Clinical	209082	OVERDOSE OF DRUG	----- community mental health resource centre. dr ----- overdose of citalopram and metronidazole. he had written a suicide note to his wife and claimed he had planned the attempt. on the day of the overdose he was under the influence of amphetamines, about 6 grams, and had had about 5 cans of tennants. pt stayed on the ward for a few days. his mood improved and he was also put on detox - chlordiazepoxide. he was also motivated to stop his drugs and alcohol and to continue with detox. he was discharged on the 20/11 and will be followed up by the community drug and alcohol team, he has in the past been referred to psychology and i will try to expedite this referral. i do not think he is currently suffering from a depressive illness, however feel that his main problem is his drug and alcohol

							abuse. i do not feel at the moment that he needs to be on antidepressants.

							is suffering from a mild to moderate depressive disorder. He does not hold any more active suicidal ideas at present. There seems to be an underlying alcohol problem which he is not willing to face. I advised him to continue on his current medication once he is discharged from the medical ward. I will arrange for him to have an out-patient appointment in ~~~~~ and will discuss his case with the CMHT.

							Hospital on 1st July 2002. This was after a failed suicide attempt when she tried to kill herself with an overdose comprising of 10 tablets of Temazepam each of 10mg strength. Soon after taking the overdose she panicked and called her mother by herself. Her mother soon summoned help. She said that she had been thinking of killing herself for a while. She had not left any suicidal note. At the time of assessment, she still had thoughts of, life is not worth living, but she denied having any active suicidal intent or plan. Though ----- did not identify any precipitants or difficulties which might have led her to life is not worth living her mother identified numerous reasons which she felt might have attributed to her depression. They include: recent separation from her long term boyfriend, stressors at University and a difficult relationship with her father. ----- has 10 months history of feeling low in mood and unworthy. S

Appendix 6. Variables retained in the case control analyses.

The following tables show the terms entered in the models using stepwise conditional logistic regression in the case control analyses.

- Model 1 = treatment effect only
- Model 2 = treatment*age interaction
- Model 3 = treatment*gender interaction
- Model 4 = treatment*duration interaction
- Model 5 = treatment*age groups interaction
- Model 6 = treatment*age*duration interaction

Appendix 7. Statistical models for treatment by age interaction

Modeling age as an ordinal variable in the cohort data

For the treatment comparisons: SSRI vs Non-SSRI, Paroxetine vs Other SSRIs and Paroxetine vs Fluoxetine, we attempted to model age at index date as an ordinal variable in 7 groups (10-18,19-29,30-39,40-49,50-59,60-69,70+). These tests were performed over 4 different age ranges for each treatment comparison, in order to remove outliers at the extremities should they exist.

If the defined age groups could be considered ordinal, we then went on to test the age by treatment interaction, for linear, quadratic and cubic models.

Adjacent models are compared using likelihood ratio tests.

The test for ordinality, compares the model where age is included as an ordinal variable (1-7) against the model where age is unordered categories. If the unordered age categories explain the data significantly ($p < 0.05$) better than ordinal age, no further modeling was done within that treatment/age range strata.

Only 4 of the 12 tests led to further modeling. Within these four strata, no treatment by age interactions were found to be significant, regardless of the model type (linear, quadratic or cubic).

Modeling age by treatment
 -2 Log Likelihood statistics by model and age range

test	-2 Log Likelihood				
	Age as groups	Age as linear variable	Linear age by trt interaction	Quadratic age by trt interaction	Cubic age by trt interaction
